Immobilization Study

• Men and Women
• Ages 18-50
• Non-surgical treatment
• Immobilized 4-6 weeks
• No injury to contralateral limb

Ankle Immobilization Study

Department of Physical Therapy

Department of Orthopaedics

University of Florida
Muscle atrophy and weakness are common clinical phenomena observed following immobilization. The impact of immobilization can impact activities of daily living and lead to functional limitations and even disability.

Research is being conducted at the University of Florida to identify ways to improve rehabilitation following ankle or foot injuries. The goal of this project is to learn more about certain genetic and biological factors which may play a role in the differences among individuals in how muscles recover following immobilization.

If you have injured your foot or ankle that required immobilization for at least 4 weeks, you may be eligible to participate in this study.

As part of this study you will receive 6 weeks of rehabilitation as part of standard orthopedic treatment. Additional tests include muscle strength testing, MRI, muscle biopsies, blood samples and functional performance testing.
